

# Matrix and Linear Algebra

David Robinson

## Linear Equations in Linear Algebra

A matrix is in **echelon form** if:

1. All nonzero rows are above any rows of all zeros.
2. Each leading entry of a row is in a column to the right of the leading entry of the row above it.
3. All entries in a column below a leading entry are zeros.

A matrix is in **reduced echelon form** if:

1. It is in echelon form.
2. The leading entry in each nonzero row is 1.

### Properties

- Two matrices are row equivalent if there exists a sequence of elementary row operations that transforms one matrix into the other.
- Each matrix is row equivalent to only one reduced echelon matrix.
- The echelon form of a matrix is not unique, but the reduced echelon form is unique.

## Existence and Uniqueness Theorem

A linear system is consistent if the rightmost column of echelon form of the augmented matrix is not a pivot column.

## Row Reduction Algorithm

The row reduction algorithm leads directly to an explicit description of the solution set of a linear system when the algorithm is applied to the augmented matrix of the system, leading to a general solution of a system.

1. Forward Phase (reducing a matrix to echelon form)

- (a) Begin with the leftmost nonzero column. This is a pivot column. The pivot position is at the top.
  - (b) Select a nonzero entry in the pivot column as a pivot. If necessary, interchange rows to move this entry into the pivot position.
  - (c) Use row replacement operations to create zeros in all positions below the pivot.
  - (d) Ignore the row containing the pivot position and all rows above it.
  - (e) Repeat until there are no more nonzero rows to modify.
2. Backward Phase (reducing a matrix to reduced echelon form)
- (a) Beginning with the rightmost pivot and working upward and to the left, create zeros above each pivot. If a pivot is not 1, make it 1 by a scaling operation.

## Span (Linear Combination)

- The span of two vectors,  $\text{Span}\{\mathbf{v}_1, \mathbf{v}_2\}$ , represents all vectors that can be reached by scaling and adding the two vectors.
- If the system consisting of vectors  $\mathbf{v}_1$ ,  $\mathbf{v}_2$ , and  $\mathbf{b}$  is consistent, then  $\mathbf{b}$  is in  $\text{Span}\{\mathbf{v}_1, \mathbf{v}_2\}$ .
- A matrix can only span  $\mathbb{R}^n$  if it has pivot positions in  $n$  rows.

## Matrix Equation $A\mathbf{x} = \mathbf{b}$

$A\mathbf{x} = \mathbf{b}$  can be represented as a vector or matrix equation.

$$\begin{aligned} ax_1 + bx_2 + cx_3 &= d \\ ex_1 + fx_2 + gx_3 &= h \end{aligned}$$

Vector Equation:

$$x_1 \begin{bmatrix} a \\ e \end{bmatrix} + x_2 \begin{bmatrix} b \\ f \end{bmatrix} + x_3 \begin{bmatrix} c \\ h \end{bmatrix} = \begin{bmatrix} d \\ h \end{bmatrix}$$

Matrix Equation:

$$\begin{bmatrix} a & b & c \\ e & f & g \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} d \\ h \end{bmatrix}$$

Augmented Matrix:

$$\begin{bmatrix} a & b & c & d \\ e & f & g & h \end{bmatrix}$$

Let  $A$  be an  $m \times n$  matrix. Then the following statements are logically equivalent. That is, for a particular  $A$ , either they are all true statements or they are all false.

1. For each  $\mathbf{b}$  in  $\mathbb{R}^m$ , the equation  $A\mathbf{x} = \mathbf{b}$  has a solution.
2. Each  $\mathbf{b}$  in  $\mathbb{R}^m$  is a linear combination of the columns of  $A$ .
3. The columns of  $A$  span  $\mathbb{R}^m$ .
4.  $A$  has a pivot position in every row.

## Homogeneous Equation

A homogeneous equation is a linear equation in the form  $Ax = 0$

1. The homogeneous equation always has at least one solution (the trivial solution), where  $\mathbf{x} = \mathbf{0}$ .
2. The homogeneous equation has a nontrivial solution if the equation has at least one free variable.
3. If the matrix  $\mathbf{A}$  has more columns than rows ( $n > m$ ), the system often has infinitely many solutions.
4. If  $\mathbf{A}$  has  $n$  pivot columns, the columns of  $\mathbf{A}$  are linearly independent, since every variable is a basic variable.

## Parametric Vector Equation

The equation can be represented in parametric vector form if there is a free variable so that all of the other variables are represented in terms of the free variable. For example, if  $x_3$  is a free variable in  $\mathbb{R}^3$ ,

$$x = \begin{bmatrix} c \\ d \\ 0 \end{bmatrix} + x_3 \begin{bmatrix} a \\ b \\ 1 \end{bmatrix}$$

where  $x_1 = ax_3 + c$  and  $x_2 = bx_3 + d$ .

$$x = \begin{bmatrix} a + bx_3 \\ c + dx_3 \\ e + fx_3 \end{bmatrix}, \text{ geometrically describes a line through } \begin{bmatrix} a \\ c \\ e \end{bmatrix} \text{ parallel to } \begin{bmatrix} b \\ d \\ f \end{bmatrix}$$

The solution set of  $A\mathbf{x} = \mathbf{b}$  is the set of all vectors of the form  $\mathbf{w} = \mathbf{p} + \mathbf{v}_h$ , where  $\mathbf{v}_h$  is any solution of the equation  $A\mathbf{x} = \mathbf{0}$ , only when the equation  $A\mathbf{x} = \mathbf{b}$  is consistent for some given  $\mathbf{b}$ , and there exists a vector  $\mathbf{p}$  such that  $\mathbf{p}$  is a solution.

## Linear Independence

An indexed set of vectors  $\{\mathbf{v}_1, \dots, \mathbf{v}_p\}$  in  $\mathbb{R}^n$  is said to be linearly independent if the vector equation  $x_1\mathbf{v}_1 + \dots + x_p\mathbf{v}_p = \mathbf{0}$  has only the trivial solution.

- If a set  $S = \{\mathbf{v}_1, \dots, \mathbf{v}_p\}$  in  $\mathbb{R}^n$  contains the zero vector, then the set is linearly dependent.
- Two vectors are linearly dependent if they live on a line through the origin.

## Linear Transformations

A linear transformation is a function from  $\mathbb{R}^n$  to  $\mathbb{R}^m$  that assigns to each vector  $\mathbf{x}$  in  $\mathbb{R}^n$  a vector  $T(\mathbf{x})$  in  $\mathbb{R}^m$ . For a transformation to be linear, then:

- $T(\mathbf{0}) = \mathbf{0}$ .
- $T(c\mathbf{u} + d\mathbf{v}) = cT(\mathbf{u}) + dT(\mathbf{v})$

### Key Points

- If  $A$  is a  $m \times n$  matrix and  $T$  is a transformation defined by  $T(\mathbf{x}) = A\mathbf{x}$ , then the domain of  $T$  is  $\mathbb{R}^n$  and the range of  $T$  is the solution set.
- A mapping  $T: \mathbb{R}^n \rightarrow \mathbb{R}^m$  is one-to-one if each vector in  $\mathbb{R}^n$  maps onto a unique vector in  $\mathbb{R}^m$ . Also,  $T$  is one-to-one if and only if the columns of  $A$  are linearly independent.
- A mapping  $T: \mathbb{R}^n \rightarrow \mathbb{R}^m$  is onto  $\mathbb{R}^m$  if every vector in  $\mathbb{R}^m$  is mapped onto by some vector  $\mathbf{x}$  in  $\mathbb{R}^n$ . Also,  $T$  is onto  $\mathbb{R}^m$  if there are  $n$  pivot columns.

Standard matrix of  $T$  to rotate points about the origin by  $\theta$ :  $A = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}$

If  $T: \mathbb{R}^n \rightarrow \mathbb{R}^m$  is a linear transformation, then there exists a unique matrix  $A$  such that the following equation is true.

$$T(\mathbf{x}) = A\mathbf{x} \text{ for all } \mathbf{x} \text{ in } \mathbb{R}^n$$

In fact,  $A$  is the  $m \times n$  matrix whose  $j$ th column is the vector,  $T(e_j)$ , where  $e_j$  is the  $j$ th column of the identity matrix in  $\mathbb{R}^n$ , as shown in the following equation.

$$A = [T(e_1) \quad \dots \quad T(e_n)]$$

## Matrix Multiplication

The definition of matrix multiplication states that if  $A$  is an  $m \times n$  matrix and  $B$  is an  $n \times p$  matrix with columns  $\mathbf{b}_1, \dots, \mathbf{b}_p$ , then  $AB = [A\mathbf{b}_1 \quad \dots \quad A\mathbf{b}_p]$ .

$$\begin{bmatrix} a & b \\ c & d \\ e & f \end{bmatrix} \times \begin{bmatrix} g & h \\ i & j \end{bmatrix} = \begin{bmatrix} ag + bi & ah + bj \\ cg + di & ch + dj \\ eg + fi & eh + fj \end{bmatrix}$$

The  $(i, j)$  entry in  $AB$  is

$$\sum_{k=1}^n a_{ik}b_{kj} \quad \text{or} \quad a_{i1}b_{1j} + \cdots + a_{in}b_{nj}$$

$$(AB)^T = B^T A^T$$

### Key Points

- Matrix multiplication is only allowed for matrices where the number of columns in the first matrix equal the number of rows in the second matrix.
- If  $A$  is a  $a \times b$  matrix and  $B$  is a  $b \times c$  matrix, then  $AB$  is a  $a \times c$  matrix.
- Given a square  $n \times n$  matrix  $A$ , there are infinite matrices for  $B$  in  $AB = BA$  because any multiple of  $I_n$  will satisfy the equation.
- The definition of  $AB$  states that each column of  $AB$  is a linear combination of the columns of  $A$  using weights from the corresponding column of  $B$ .

## Inverse Matrices

$$A \times A^{-1} = I$$

where  $A$  is an invertible matrix,  $A^{-1}$  is the inverse of  $A$ , and  $I$  is the identity matrix with the same shape as  $A$ . Calculating the inverse of a  $2 \times 2$  square matrix.

### Calculating the Inverse of a Matrix

1. Start with a square matrix  $A$ .
2. Reduce the matrix  $\begin{bmatrix} A & I \end{bmatrix}$  (where  $I$  is the identity matrix with the same shape as  $A$ ) to reduced echelon form which will result in  $\begin{bmatrix} I & A^{-1} \end{bmatrix}$ .

If  $A$  is a  $2 \times 2$  matrix, then  $A^{-1} = \frac{1}{ad-bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$ .

If  $A$  is an invertible  $n \times n$  matrix, then for each  $\mathbf{b}$  in  $\mathbb{R}^n$ , the equation  $A\mathbf{x} = \mathbf{b}$  has the unique solution  $\mathbf{x} = A^{-1}\mathbf{b}$ .

## Invertible Matrix Theorem

The following statements are either all true or all false

1.  $A$  is an invertible matrix.
2.  $A$  has  $n$  pivot positions.
3. The columns of  $A$  form a linearly independent set.
4. The columns of  $A$  span  $\mathbb{R}^n$ .
5. There are  $n \times n$  matrices  $C$  and  $D$  such that  $CA = I$  and  $AD = I$ .

The determinant of a standard  $n \times n$  matrix is  $ad - bc$ .

### Key Points

- $(AB)^{-1}$  is  $B^{-1}A^{-1}$ .
- If  $A$  is an invertible  $n \times n$  matrix, then the equation  $A\mathbf{x} = \mathbf{b}$  is consistent for each  $\mathbf{b}$  in  $\mathbb{R}^n$  because  $A^{-1}\mathbf{b}$  exists for all  $\mathbf{b}$  in  $\mathbb{R}^n$  and  $\mathbf{x} = A^{-1}\mathbf{b}$ .
- The columns of an  $n \times n$  matrix  $A$  are linearly independent when  $A$  is invertible because the equation  $A\mathbf{x} = \mathbf{0}$  has the unique solution  $\mathbf{x} = \mathbf{0}$ .
- The product of invertible matrices is also invertible.
- If  $A$  and  $B$  are  $n \times n$  matrices and  $AB$  is invertible, then  $B$  is also invertible

## Other

1. It is not possible that  $CA = I_4$  for some  $4 \times 2$  matrix  $C$  when  $A$  is a  $2 \times 4$  matrix because if it were true, then  $CA\mathbf{x}$  would equal  $\mathbf{x}$  for all  $\mathbf{x}$  in  $\mathbb{R}^4$ . Since the columns of  $A$  are linearly dependent as there are more columns than rows,  $A\mathbf{x} = \mathbf{0}$  for some nonzero vector  $\mathbf{x}$ , so  $\mathbf{x} = I\mathbf{x} \neq CA\mathbf{x} = \mathbf{0}$ .
